

Geographic information system (GIS)

DevMan's geographic information system (GIS) is a comprehensive database of postal codes, municipal areas and provinces seamlessly integrated from Google Maps. Single data source means data is consistent.

When you enter the address country and postal code of your contact, the region is automatically populated with the correct region from the GIS database. Any records linked to the profile will inherit the locality – projects, bursaries, approaches, pledges, donations and payments.

How it works

- Addresses are captured on contact profiles.
- Up to three addresses can be added, physical, postal, mailing / other.
- The address can be auto filled by using the Google address look up feature.
- Using the GIS auto feature on linked project and financial records will auto add the locality based on the linked contact.
- If the GIS changes on the contact, linked projects set to auto will be updated. Finance records will not be updated.
- Address labels will format according to the country's postal requirements. Eg, the country will default to South Africa and will not add the province if your DevMan site is South African based for PAMS compliance.
- Where postal codes match more than one country the country can be specified.

Reports

With consistent data reports are more accurate.

- View lists of your contacts, projects and financial records right down to municipal areas*
- View data statistically
- View interactive maps pinpointing locations

*DevMan supports GIS databases for South Africa, Australia and USA. UK coming soon.
